12

13 **Abstract:** The volatile constituents of drug samples derived from *Cannabis sativa L.* were
14 investigated by means of headspace solid phase microextraction (HS-SPME) and gas
15 chromatography techniques (GC-MS, GC × GC-MS). Samples of cannabis herb and hashish
16 showed clear differences in their volatile chemical profiles, mostly resulting from photo-
17 oxidation processes occurring during the transformation of fresh cannabis herb into hashish.
18 Most unexpectedly, we could demonstrate hashish samples as containing remarkable amounts
19 of a rare and unusual monoterpene—5,5-dimethyl-1-vinylbicyclo[2.1.1]hexane—among the
20 volatile compounds detected in their headspaces. We gave evidence for the formation of this
21 compound from the light induced rearrangement of β-myrcene during the manufacture of
22 hashish. In view of its high abundance among volatile constituents of cannabis resin and its
23 scarce occurrence in other natural volatile extracts, we propose to rename this specific
24 monoterpene hashishene.

25

26 **Keywords:** *Cannabis sativa L.*, hashish, volatile marker, myrcene rearrangement, photo-
27 oxidation processes.

28 **1. Introduction**

29 Among all drugs of abuse, cannabis remains the most consumed worldwide under all of its
30 various forms (marijuana, hashish, cannabis oil). Cannabis is particularly popular in western
31 countries owing to its low price compared to other common illegal drugs, and it is commonly
32 considered as a drug of lower impact since discussions about bringing it to legality are still
33 ongoing in some European countries. The resin of *Cannabis sativa* L. known as hashish is a
34 product of interest for drug dealers because of its malleability that allows easy concealment
35 and transportation, and its high content of psychoactive principle (THC) compared to the raw
36 herb. It is produced in various countries around the world but the main producers are
37 undoubtedly Morocco and Afghanistan [1-4]. Hashish is produced via a relatively long
38 cottage industry process that consists in successively drying, sieving, and finally pressing the
39 resin-rich buds of cannabis plants that have been harvested at full blooming stage. It results in
40 a medium hard greenish-brownish paste that softens upon heating. The demand for hashish is
41 still high in Europe, making its illegal market a major concern for European authorities,
42 requiring more and more means for efficient traffic control.

43 Research of illegal drugs by customs squads at borders or during police controls usually
44 requires canine assistance for detection of target substances. The use of trained dogs is
45 currently the most efficient mean for rapid drug detection but has a certain drawback since a
46 dog provides a working time limited to a few hours a day. Moreover, the high cost of a canine
47 team is also the reason why people have long sought to replace, or rather say, complement
48 detection dogs by the use of electronic devices designed for the specific detection of illicit
49 substances such as drugs and explosives. While different ways to carry out detection are
50 possible, those addressing target-associated volatile organic compounds are more likely to
51 mimic canine recognition processes [5-7], and doing so, to reach low detection limits,
52 provided that the chosen analytical technology is sensitive enough, robust, and reliable. The
53 identification of specific and stable-in-time volatile target markers is therefore of crucial
54 importance in this field of technological applications.

55 In this frame, we undertook the chemical investigation of different forms of cannabis (fresh
56 and dried herb, and hashish) in order to search for potential candidates intended to trigger
57 remote detection of cannabis derived products. The volatile constituents of *Cannabis sativa* L.
58 have been explored since the early developments of gas chromatography [8]. Nearly all
59 studies published to date have reported the existence of a complex mixture of mono- and

60 sesquiterpenic derivatives. Surprisingly, while the headspace chemical composition of
61 cannabis herb is now well documented, hashish has received much less attention. We
62 therefore want to report on a multi-directed parallel analysis of various forms of cannabis by
63 means of headspace sampling methods and hyphenated GC techniques (GC-MS, GC × GC-
64 MS). Our investigations led us to observe noticeable differences between cannabis herb and
65 hashish samples, and eventually, to identify a new volatile marker in hashish.

66

67 **2. Experimental**

68 *2.1. Chemicals and products*

69 Samples of resins and herb of *Cannabis sativa* L. were obtained from the *French Police*
70 *Forensic Institute (INPS, Ecully - France)*. All chemicals and solvents were purchased from
71 Sigma-Aldrich (Illkirch, France) and used without further purification otherwise stated.

72 *2.2. Extraction of hashish and isolation of the terpenic fraction*

73 15 g of hashish (probably originating from Morocco¹) were extracted in a 200 mL Soxhlet
74 apparatus with 250 mL of pentane for 5 hours. The resulting extract (~10 g) mainly contained
75 cannabinoids and was subsequently chromatographed on silica gel with eluents of increasing
76 polarity. The first fraction (1.1 g), eluted with pentane, contained mostly monoterpenes and
77 sesquiterpenes, accompanied with a limited series of diterpenes. In this fraction, compound **11**
78 accounted for ~4.5% of the total chromatogram area, as determined by GC-MS analysis.

79 *2.3. SPME analysis*

80 100% Polydimethylsiloxane (PDMS; 100 µm) and Divinylbenzene/Carboxen/Polydimethyl-
81 siloxane (DVB/CAR/PDMS; 50/30 µm) SPME fibers were purchased from Supelco Europe.
82 Optimized parameters for SPME analyses (incubation/extraction time/temperature, nature of
83 the fiber coating) were selected following an experimental design inspired from a
84 methodology described by Vanot and Sergent [9].

85

87 2.4. Gas chromatography-mass spectrometry (GC-MS)

88 GC-MS analyses were run on two GC-MS systems. For SPME analyses, gas chromatographs
89 were operated in splitless mode with a constant flow (1 mL/min) of helium. For other routine
90 analyses, GC systems were operated in split mode (1/50). At UNS, an Agilent 6890N/5973N
91 GC-MS system was equipped with a J&W HP-1 capillary column (50 m × 0.2 mm; 0.33 µm
92 film thick.) and operated as follows: initial oven temperature, 50 °C, then increased to 250 °C
93 with a constant rate of 2 °C/min. At INPS, an Agilent 7890A/5975C system was mounted
94 with a Varian VF-1MS capillary column (50 m × 0.25 mm; 0.25 µm film thick.) and operated
95 as follows: initial oven temperature, 60 °C, then increased to 250 °C with a constant rate of
96 3 °C/min. For both systems, the transfer-line temperature was set at 280 °C. Electron impact
97 mass spectra were acquired over a 35–350 m/z range. Volatile constituents were identified
98 upon cross-correlation of their retention indices (RI) calculated from a series of *n*-alkanes, and
99 their mass spectra matched against commercial libraries (Wiley275, NIST08, MassFinder
100 2.1) or in-house MS databases built from literature information [10,11] and isolated or
101 synthesized substances whenever possible.

102 2.5. Comprehensive two-dimensional gas chromatography-mass spectrometry (GC × GC-MS)

103 GC × GC-MS analyses were performed using an Agilent 6890N/5973N GC-MS system
104 equipped with a GC × GC ZOEX kit (cryogenic dual jet/loop modulator and a secondary oven
105 installed in the main GC oven). The two-dimensional GC column set was composed of a
106 Varian VF-5MS (30 m × 0.25 mm; 0.2 µm film thick.; referred to as column 1) and a J&W
107 DB-Wax (1.25 m × 0.10 mm; 0.1 µm film thick.; referred to as column 2) coupled through a
108 deactivated fused silica capillary tube (1.25 m × 0.10 mm) installed as a loop passing twice
109 the cryogenic modulator. Column flow (He) 0.8 mL/min; Splitless injection mode;
110 temperature program for oven #1: 50 °C (5 min isotherm.) to 250 °C at 4 °C/min (20 min
111 isotherm.); temperature program for oven #2: 60 °C (5 min isotherm.) to 252 °C at 8 °C/min
112 (46 min final isotherm.). Modulation time, $P_M = 5.5$ s. The mass spectrometer was operated at
113 70 eV in fast scan mode (10 000 amu/s) over a 50–250 m/z range, giving a 24.67 Hz
114 acquisition rate. Volatile constituents were identified upon cross-correlation of their retention

115 indices calculated from a series of *n*-alkanes, and their mass spectra matched against
116 commercial libraries (Wiley275, NIST08) or in-house MS databases built from literature
117 information, and isolated or synthesized substances whenever possible.

118 *2.6. Enantioselective gas chromatography*

119 Separation of the two enantiomers of 5,5-dimethyl-1-vinylbicyclo[2.1.1]hexane **11** was
120 carried out using a Macherey-Nagel Hydrodex β-6TBDM capillary column mounted on a
121 Agilent 6890N/5973N GC-MS system. Split ratio 1/100; Oven temperature program: 80 °C to
122 220 °C at 2 °C/min. Constant flow of helium: 1.0 mL/min. MS parameters were used as
123 described above for SPME experiments.

124 *2.7. UV-mediated synthesis of 5,5-dimethyl-1-vinylbicyclo[2.1.1]hexane **11***

125 Compound **11** was synthesized according to a protocol inspired from Liu and Hammond [12].
126 Typically, a mixture of β-myrcene (1.63 g; 12 mmol) and 2-acetylnaphthalene (23 mg) was
127 dissolved in 70 mL of dry diethylether and placed in reactor system equipped with a medium
128 pressure UV lamp (Heraeus, Germany). The mixture was irradiated under argon atmosphere
129 until reaching total consumption of β-myrcene as monitored by GC analysis of aliquots
130 withdrawn from the reaction mixture. The solvent was carefully removed under vacuum, and
131 the crude product was obtained as nearly colorless oil. (crude yield > 90%; ~67% GC purity).
132 The reaction was repeated several times and all crude products combined in order to increase
133 the amount of material for distillation. A mixture of crude reaction products (12.5 g) was
134 submitted to distillation under reduced pressure. Compound **11** (6.5 g) was isolated with 87%
135 purity (bp 50 °C under 0.3 mbar) and subsequently separated by column chromatography with
136 AgNO₃-impregnated silica gel for structural elucidation by NMR (see Figures S2-7 in
137 supporting information).

138 *2.8. Nuclear magnetic resonance*

139 High resolution NMR spectra were recorded in CDCl₃ at 298 K on a Bruker Avance DRX
140 500 spectrometer operating at 500.13 MHz for ¹H and 125.76 MHz for ¹³C. In order to
141 increase sensitivity, ¹³C-NMR spectra such as broadband-¹³C and JMOD were run with a
142 direct probe head (5 mm PADUL ¹³C-1H Z-GRD). 1D- and 2D-NMR spectra such as 1H,
143 COSY, NOESY, HSQC, HMBC were run with an inverse probe head (5 mm PHTXI ¹H-
144 ¹³C/¹⁵N ZGRD). Spectrum calibration was performed by using CDCl₃ signal as internal

145 reference (7.26 ppm for ^1H , 77.16 ppm for ^{13}C). Chemical shifts (δ) are expressed in parts per
146 million (ppm) and coupling constants (J) in hertz. All NMR experiments were carried out
147 using pulse sequences supplied by the spectrometer manufacturer (Bruker TopspinTM) and
148 processed via Mestrelab MestreNOVA software (v6.0.2-5475). All spectra are given as
149 supplementary data.

150

151 **3. Results and discussion**

152 *3.1. Headspace sampling of volatile constituents*

153 In relation with its psychotropic activity, *Cannabis sativa* L. has been mainly studied for the
154 determination of its content in cannabinoids. A large variety of molecules has been reported
155 within this family [13,14], and the most representative are cannabidiol (CBD), cannabinol
156 (CBN), and Δ^9 -tetrahydrocannabinol (Δ^9 -THC) which is known as the main psychoactive
157 principle of the drug [15]. In comparison with cannabinoid derivatives, the volatile
158 constituents of cannabis have received much less attention. Nevertheless, the chemical
159 composition of the volatile fraction of cannabis derived products is well documented and has
160 been mainly established through the analysis of their essential oils [16-25] or by means of
161 headspace sampling techniques [25-29]. Hence, a large variety of volatile compounds
162 representing all chemical classes (hydrocarbons, alcohols, ketones, esters) has been detected
163 in cannabis samples [20]. Some authors also attempted to establish a chemical profile for each
164 form of cannabis, and eventually determined a more or less steady odour that could be used as
165 a chemical basis for detection of cannabis in the frame of criminal investigations [21]. Most
166 of the time, those studies reported a high content of monoterpenes and sesquiterpenes. Among
167 the monoterpene family, α - and β -pinene, β -myrcene, and limonene were the most cited
168 instances, while β -caryophyllene and α -humulene were reported as predominant in
169 sesquiterpenes. A quick overview of the main terpenoids reported as volatile constituents of
170 *Cannabis sativa* L. is given in Table S1 (see supporting information).

171 Indeed, the chromatographic profile of a cannabis sample strongly depends on 1) its nature
172 and 2) the method applied for extraction of its volatile constituents. Essential oils extracted
173 from fresh cannabis herb were previously reported to show a chemical composition
174 qualitatively similar to that obtained from air-dried herb, but that drying resulted in a loss of
175 the most volatile compounds, particularly affecting the content in monoterpenes [21].

176 Moreover, the direct comparison of the chemical composition of a cannabis essential oil with
177 that of a headspace sample is not often straightforward since thermolabile or water-sensitive
178 constituents might be dramatically affected by hydrodistillation [25,26].

179 Consequently, methods involving headspace sampling appear as the most opportune option to
180 investigate cannabis samples in order to obtain representative profiles of their volatile
181 constituents, but also allow avoiding interferences potentially brought by the predominant
182 cannabinoids in the resulting chromatograms. Headspace sampling is usually carried out by
183 using gas-tight syringes, sorbent materials placed in glass/metal tubes for purge-and-trap, or
184 SPME fibers. Direct headspace sampling and purge-and-trap methods actually give a
185 representative profile of the volatile constituents emitted by a sample but usually require
186 sampling large volume of gas, and involve the use of specific analytical equipment
187 (headspace autosampler, large volume injectors, thermodesorption units, PTV). In contrast,
188 HS-SPME allows an easier analytical setup since it can be run on any GC system with
189 minimal modifications. However, the chromatographic profiles obtained after SPME actually
190 depend on the nature of the fiber selected for extraction, and other parameters such as
191 temperature and time allowed for sample incubation/extraction, so that an optimization step is
192 often necessary to define the best conditions prior to GC analysis.

193 In our case, this optimization step was carried out by following a simple design of experiment
194 (DoE) according to a protocol inspired by Vanot and Sergent [9]. We applied this procedure
195 to the analysis of hashish samples in order to define the best operating conditions for
196 extraction of their volatile constituents. We decided to evaluate the influence of five
197 parameters at two different levels (Table S2-4; see supporting information). It resulted in the
198 Hadamard matrix presented in Table S3. The results of the experimental design enlightened
199 the crucial influence of the temperature applied for incubation and extraction (X3) (Table S4).
200 Hence, an increase of temperature generally resulted in higher signal abundance (Fig. 1a), and
201 not surprisingly, in conjunction with a longer time of extraction (X5), sesquiterpenes were
202 predominantly concentrated on the fiber (Fig. 1b). In order to be compliant with remote
203 sensing scenarii, and because the most volatile constituents are more likely to be detected in
204 real field measurements, we selected the parameters allowing for a better preconcentration of
205 monoterpenes. Consequently, the highest selectivities for monoterpene extraction were
206 obtained when analyses were performed at room temperature while the extraction time was
207 limited to 20 min (exp. 7 and 8). The nature of the fiber had here a limited effect as well as the
208 incubation time. Optimal conditions deduced from in Figure 1b were used to investigate

209 various cannabis samples. Thus, samples of resin and cannabis herb (1.0 g) were allowed to
210 equilibrate in a 20 mL cap-sealed vial for 60 min at room temperature, then a 100 μ m PDMS
211 SPME fiber was used to perform the extraction of the volatile constituents at the same
212 temperature for 20 min. Representative profiles for each form of cannabis are depicted in
213 Figure 2.

214

215 *3.2. Identification of an unusual monoterpene in hashish*

216 In a first series of analyses (samples 20-24; Table 5), we observed that all hashish samples
217 presented high amounts of an unusual and rare monoterpene **11** eluting well before α -pinene
218 **13**. This compound was identified as 1-vinyl-5,5-dimethyl[2.1.I]bicyclohexane by its mass
219 spectrum (Figure 3) available in only one commercial MS databank (MassFinder 4.0,
220 Germany). It was rather surprising to find **11** in such high abundance among the volatile
221 constituents of hashish samples since the natural occurrence of this compound was reported
222 only once in the past as a minor constituent (<0.1%) of the essential oil of *Mentha cardica L.*
223 [30].

224 In order to go in further details, a second series of analyses was performed with a higher
225 number of samples at the forensic department of the French Institute of scientific police
226 (INPS, Ecully, France). In total, 11 samples of hashish and 10 samples of cannabis herb (fresh
227 and dried) were investigated by means of HS-SPME-GC-MS (Figure 4). In almost all hashish
228 samples, compound **11** was detected among the most abundant volatile compounds present in
229 the headspace, ranging from 1.1 to 14.9% (median value: 10.2 %), while it was detected either
230 at trace levels or in low amounts in fresh and dried herb (Table 1).

231 Not surprisingly, the literature related to the GC-MS analysis of cannabis (essential oil and
232 headspace constituents) does not contain any mention of **11** among all the previously
233 identified volatile constituents. In contrast, other common monoterpenes (α -pinene **13**, β -
234 pinene **24**, limonene **37**) and sesquiterpenes (β -caryophyllene **159** and α -humulene **168**) were
235 frequently reported as abundant. Among them, β -myrcene **25**, a monoterpene widespread in
236 essential oils, has often been cited as a major volatile constituent and has thus been proposed
237 as specific marker of cannabis and marijuana [21,22,25]. As a matter of fact, among the
238 samples of cannabis herb investigated in here, seven out of ten contained huge amounts of β -
239 myrcene (19.5-28.7 %).

240 Interestingly, compound **11** was previously reported as a UV light-mediated rearrangement
241 product of **25** when irradiated in presence of sensitizers such as 2-acetylnaphthalene,
242 benzophenone, or clay-supported materials [12,31-33] (Figure 5). Yet the literature related to
243 **11** is scarce since only 6 bibliographic references dealing mainly with its synthetic preparation
244 can be found registered by the Chemical Abstract Service (as observed by using SciFinder)
245 [12,31-34].

246 Quite obviously, the intriguing high abundance of **11** in hashish samples led us to assume that
247 its presence was directly linked with the high abundance of **25** in samples of fresh cannabis
248 herb. As already mentioned, hashish is manufactured according to a lengthy process involving
249 repetitive steps of sieving and drying of the resin-rich female heads of cannabis plants. The
250 process is carried out until the resin naturally aggregates, producing hashish after a final
251 compression [2,4]. Any exposure to sunlight during those drying steps could therefore be
252 reasonably considered responsible for the photolytic formation of **11** from **25**.

253 Several experiments were additionally performed to ensure that the presence of **11** was not
254 due to any potential artifact related to the chosen analytical procedure. Therefore, 15 g of
255 hashish were extracted in a Soxhlet apparatus by using dichloromethane as a solvent, then the
256 concentrated extract was separated by column chromatography in order to obtain the
257 hydrocarbon fraction. As observed by subsequent GC-MS analysis, **11** was detected among
258 other apolar constituents such as mono-, sesqui-, and diterpenes (dimyrcene isomers
259 essentially in the latter case). In addition, we could determine that **11** was present as a racemic
260 mixture in this fraction by means of enantioselective GC-MS (Figure 6). It thus strongly
261 supported the photolytic origin of **11**, where an enzymatic formation would have more likely
262 induced some enantiomeric excess. Any attempts of isolation were unfortunately
263 unsuccessful. Compound **11** was thus synthesized according to a protocol inspired by Liu *et*
264 *al.*[12] in order to bring final evidence for its presence as a constituent of hashish (its
265 complete characterization by 1D- and 2D-NMR is given as supplementary material to this
266 article). Owing to the rare occurrence of **11** in natural extracts and its unexpected high
267 abundance in hashish, we therefore propose to rename it hashishene.

268

269 *3.3. Investigation of photo-oxidation volatile products*

As described above, all hashish and herb samples released substantial amounts of mono- and sesquiterpene hydrocarbons in their headspace. In addition, all samples appeared as containing small amounts of oxygenated terpenoids in both series. Several of them were already detected and identified by GC-MS but the whole family could not be sufficiently investigated on the overall because of a generally high extent of coelution in this part of the chromatogram, associated with their low abundances in comparison with their hydrocarbon counterparts. We therefore aimed at using comprehensive two-dimensional gas chromatography-mass spectrometry (GC × GC-MS) in order to investigate in more detail the chemistry of hashish samples, especially regarding their composition in oxygenated derivatives. GC × GC brings several advantages compared to conventional GC, among which an increased sensitivity, a higher resolution and, eventually, the structured distribution of analytes on the 2D-plots are probably the most outstanding specific features of the technique [35-42]. Four different resins and one sample of cannabis herb were analyzed in our laboratory by means HS-SPME-GC × GC-MS. Parameters for HS-SPME were identical to those used for conventional GC-MS analysis. A comparison of the resulting two-dimensional chromatographic profiles is presented in figures 7 and 8. Both hashish and bud samples provided two distinct regions in their 2D-chromatogram, roughly corresponding to the distribution areas of monoterpenic and sesquiterpenic derivatives. A total of 186 constituents were identified in our samples (Table 2). The resulting chromatographic profiles were identical to those obtained by conventional GC-MS except that the number of identified constituents was greatly improved owing to the better resolution of the chromatograms. At first sight, hashish samples presented a greater diversity in oxygenated terpenes than cannabis herb (Figure 7). This was particularly observed in the monoterpane family where no less than 50 constituents were actually identified. Besides the common ketones and alcohols that appeared in both types of samples (linalool, α -fenchol, terpinen-4-ol, α -terpineol), hashish samples contained other minor oxygenated monoterpenes presenting higher abundances compared to the herb. Most of these alcohols, aldehydes or ketones could be structurally related to the hydrocarbons initially present in the herb. For instance, the two stereoisomers of 2-methyl-6-methylene-octa-3,7-dien-2-ol **55** and **64**, ipsdienol **79**, and 2-methyl-6-methylene-octa-1,7-dien-3-ol **86** are all derivatives of β -myrcene **25**. The same phenomenon was observed for limonene **37**, producing *trans*- and *cis*-mentha-2,8-dien-1-ol, **69** and **93**, *cis*- and *trans*-mentha-1(7),8-dien-2-ol, **109** and **122**, and *trans*- and *cis*-carveol **119** and **121**. From a general point of view, most of these oxygenated derivatives corresponded to secondary photo-oxidation products of the initial terpenes. In the presence of light and singlet oxygen, terpenes

304 are known to undergo photo-oxidation leading to the formation of allylic hydroperoxides
305 (Figure 9) [43,44]. Since hydroperoxides are generally not stable-in-time, they will generate
306 the corresponding alcohols by reductive loss of an oxygen atom. At some point, those
307 alcohols may be further oxidized into aldehydes or ketones. By considering the possibility of
308 an overall process of photo-oxidation occurring during the manufacture of hashish from
309 cannabis, we could retrace the molecular relationships existing between volatile constituents
310 of hashish and those present in cannabis herb. In view of the compounds identified by GC ×
311 GC-MS, a clear scheme of molecular transformations can now be pictured out (Figure 10).

312 Interestingly, GC × GC-MS gave us the opportunity to explore the sesquiterpene region in
313 more details. While most of the commonly reported sesquiterpenes (Table S1) were detected,
314 it was possible to observe that a complete series of caryophyllane/humulane derivatives was
315 present among hashish volatile constituents. Hence, in addition to the frequently cited
316 isocaryophyllene **156**, β -caryophyllene **159**, α -humulene **168**, and caryophyllene oxide **200**,
317 we identified three more isomers of caryophyllene, **161**, **166**, and **169**, but also various
318 (photo)-oxidation products. These compounds, somewhat rare in nature, were identified on
319 the basis of their mass spectra, in all respects comparable with those of the literature (Figure
320 S1; see supporting information) [11,43].

321 In addition to terpenic derivatives that accounted for more than 80% of the detected
322 constituents, it was possible to notice the presence of other organic compounds commonly
323 found in natural extracts such as linear alkanes, and fatty acids, esters or alcohols. Only a few
324 phthalates could actually be identified but their presence was more likely attributed to the
325 packaging used to wrap the resin (especially in case of hashish ovules; see hashish 24). Other
326 traces of unknown organic pollutions were detected but could not be considered as indicative
327 of any potential adulteration. On the overall, no significant contamination from any potential
328 cutting agent was detected. It thus gives a clue about the actual composition of cannabis resin,
329 while it is often believed that bad quality resins are often cut with undesired and/or harmful
330 substances such as wax, grease, or even rubber. Although these experiments have been
331 performed on a limited number of samples, the results obtained here are consistent with that
332 of HS-SPME-GC-MS. Moreover, GC × GC brought us the opportunity to explore in more
333 detail their volatile profiles, hence providing a deeper insight towards minor constituents.

334

335 **Conclusion**

336 The volatile constituents of *Cannabis sativa* L. have been widely studied in the past, and
337 most studies have reported the predominance of mono- and sesquiterpenes. Our analytical
338 investigations of cannabis herb and resin (hashish) led us to observe clear differences in the
339 chemical composition of their headspaces. It appeared that most of the major terpenes
340 present in fresh cannabis herb undergo various transformations during hashish manufacture,
341 including isomerization, dehydration, cyclisation, and more specifically, photo-oxidation.
342 By means of GC × GC-MS analysis, hashish samples were determined to contain a huge
343 variety of oxygenated terpenes which could be related to the initial terpenes identified in
344 fresh herb.

345 Most importantly, hashish samples were determined to contain significant amounts of a rare
346 monoterpene, 1-vinyl-5,5-dimethyl[2.1.I]bicyclohexane, that we wish to rename
347 hashishene. We demonstrated hashishene as being formed during the manufacture of
348 hashish upon photolytic rearrangement of β-myrcene, a monoterpene that is particularly
349 abundant in fresh cannabis herb. Owing to its rare natural occurrence in other essential oils
350 and to its high abundance in hashish, this compound might thus prove useful as a hashish
351 marker for remote-sensing applications.

352

353 **Acknowledgments**

354 This work has been supported by the European Union in the frame of the FP7-funded project
355 DOGGIES registered under grant agreement n°285446. DOGGIES stands for Detection of
356 Olfactory traces by orthoGonal Gas identification technologIES, and it is developed within a
357 consortium of 13 European partners. All details are available on the website <http://www.fp7-doggies.eu>.

359

360 **Note**

361 The use of 5,5-dimethyl-1-vinylbicyclo[2.1.1]hexane as volatile marker of hashish has been
362 submitted to patent protection (European patent application filed on 04/28/14 under the serial
363 number EP 14305628.1). A supporting information file containing various spectroscopic data
364 is available free of charge at the editor website.

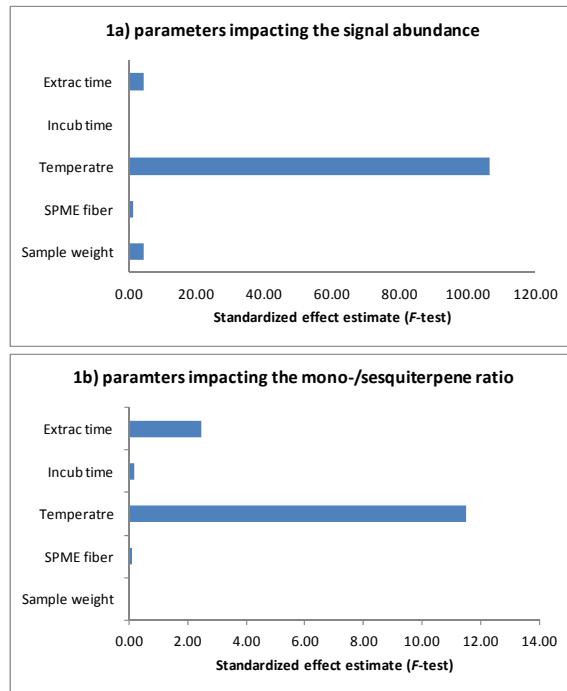

Fig. 1. Pareto charts depicting the influence of parameters studied during SPME optimisation in regard to the total signal abundance (1a) and the mono-/sesquiterpene ratio (1b). Calculation of *p*-value for temperature in each case gave 0.009 (1a) and 0.077 (1b), other parameters did not reveal significant influence with *p*-values > 0.1. (single column figure)

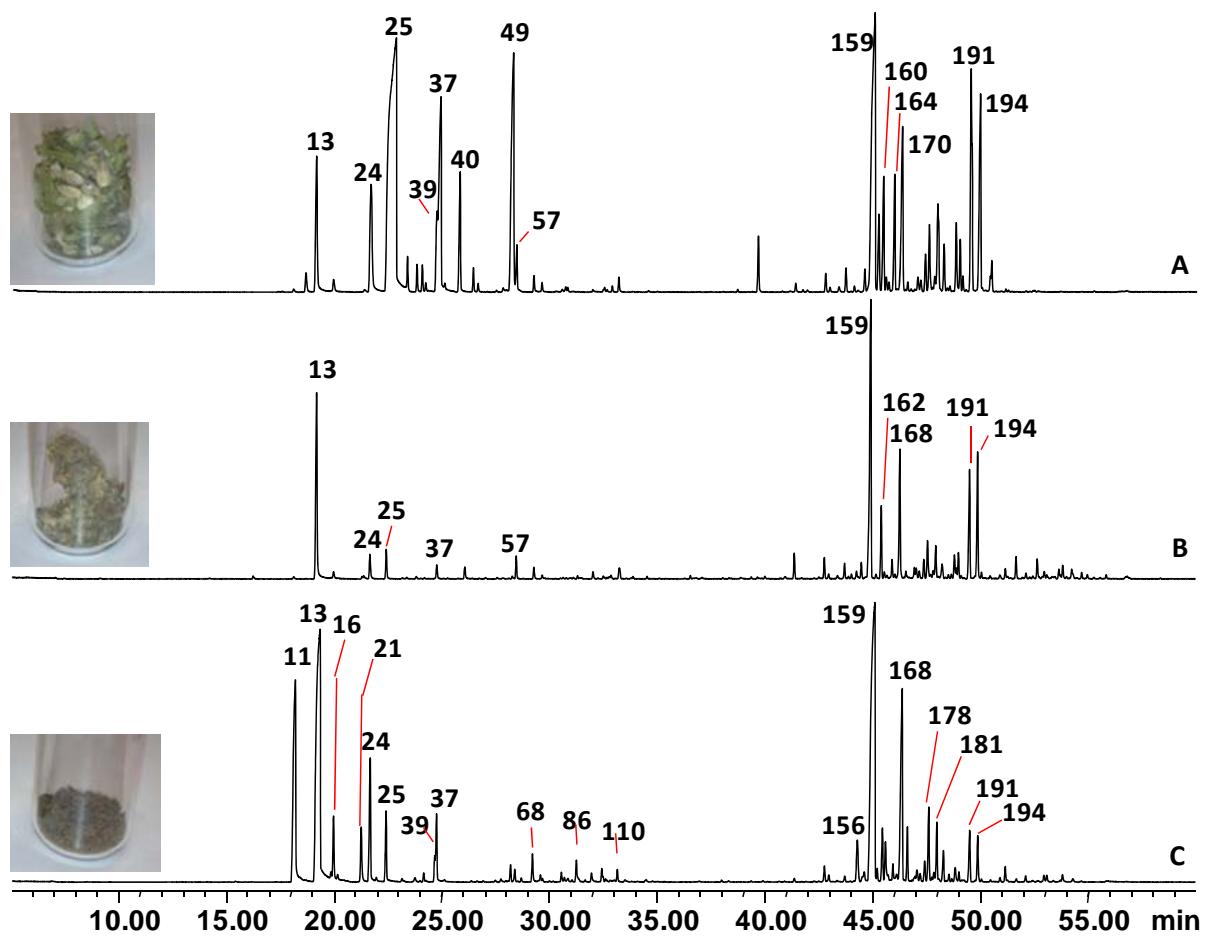

Fig. 2. Comparative HS-SPME-GCMS analyses of cannabis samples. A: fresh cannabis herb; B: dry herb; C: hashish. SPME was performed by using 100 μm PDMS fibers (Supelco). Compound numbers are given according to Tables 1 and 2. (double column figure)

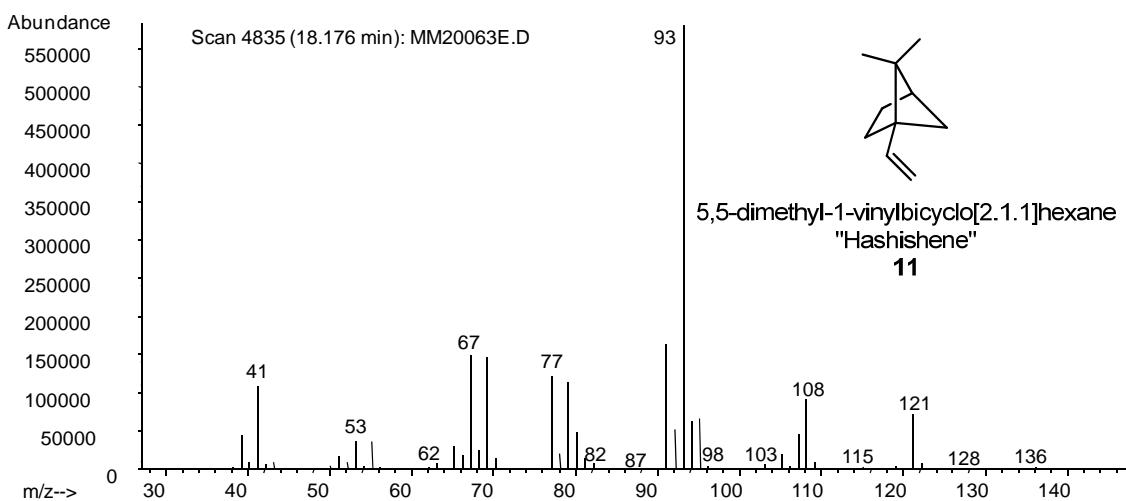

Fig. 3. Structure and EI-mass spectrum of 5,5-dimethyl-1-vinylbicyclo[2.1.1]hexane **11**.

(double column figure)

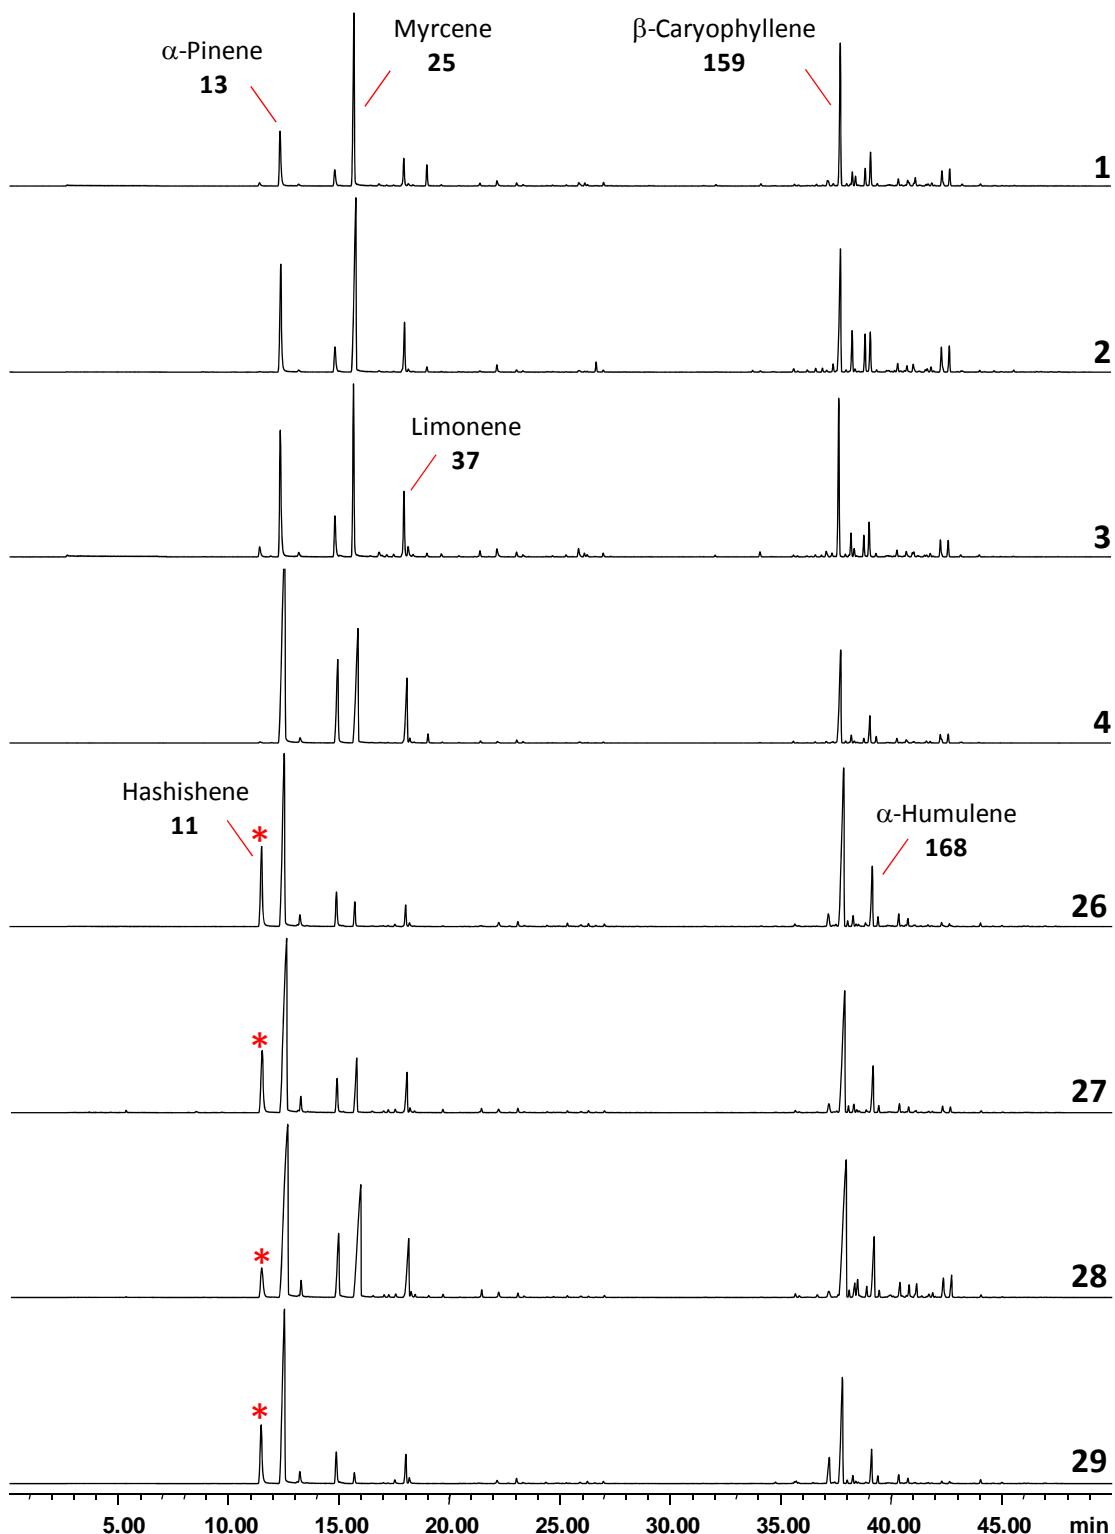

Fig. 4. Comparative HS-SPME-GCMS analyses of multiple samples of cannabis herb (1-4) and hashish (26-29) performed at the *Institut National de Police Scientifique* (Ecully, France). While several terpenes are common to all forms of cannabis, hashish samples are characterized by the presence of hashishene **11** eluting before α -pinene **13**. It is moreover interesting to notice how a great amount of myrcene **25** coincides with a smaller amount of hashishene **11** by simply comparing chromatographic profiles of hashish samples **26**, **27** and **28**. The complete description of their chemical composition is given in Table 5. (double column figure)

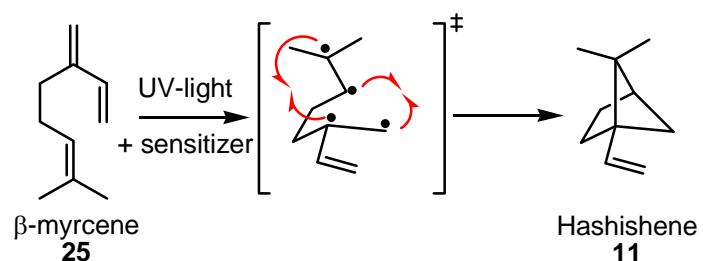

Fig. 5. UV-light mediated synthesis of hashishene **11** from β -myrcene **25**. (single column figure)

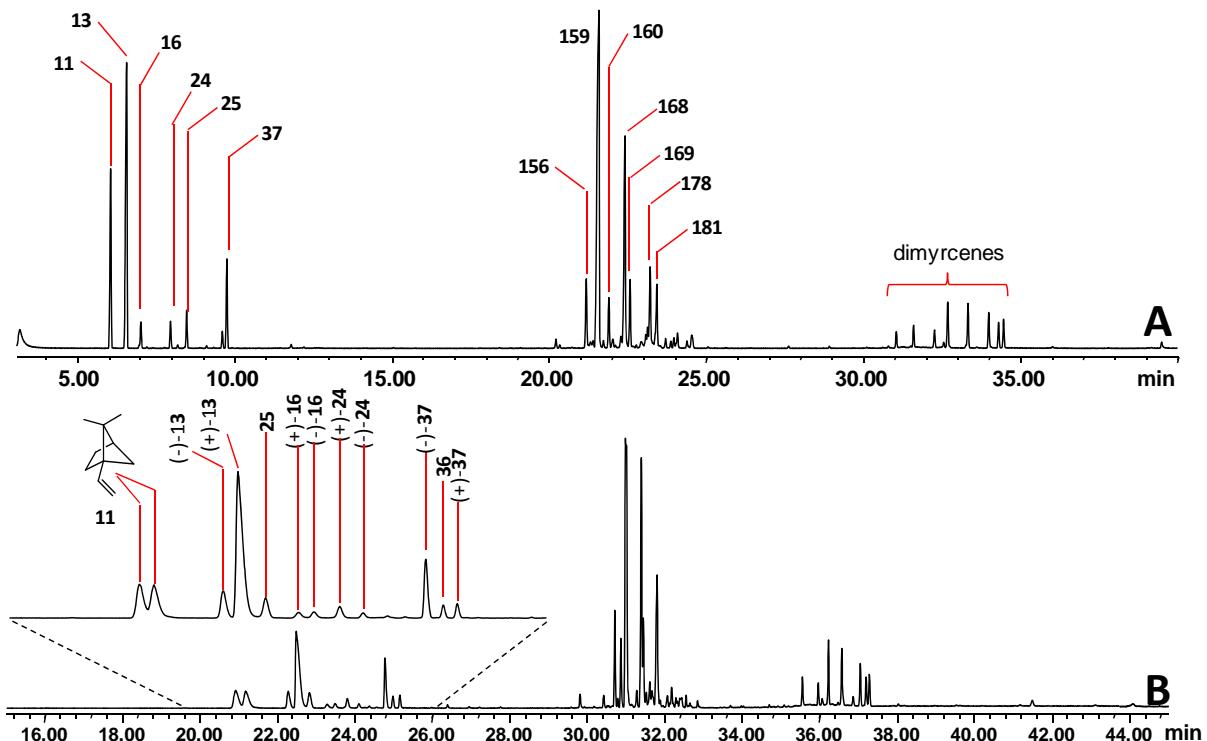

Fig. 6. GC-MS analysis of a hydrocarbon fraction obtained from hashish by Soxhlet extraction and subsequent flash column chromatography (A). Hydrocarbons were distributed in three main families including mono-, sesqui- and diterpenes (traces of *n*-alkanes could also be detected). The enantioselective GC-MS analysis of the same fraction (B) revealed that hashishene **11** was present as a racemic mixture (analysis performed on heptakis(2,3-di-*O*-methyl-6-*O*-tert-butyldimethylsilyl)- β -cyclodextrin; elution order is deduced from reference substances or literature data (see *J. Essent. Oil Res.*, **1996**, 8, 487-497)). (double column figure)

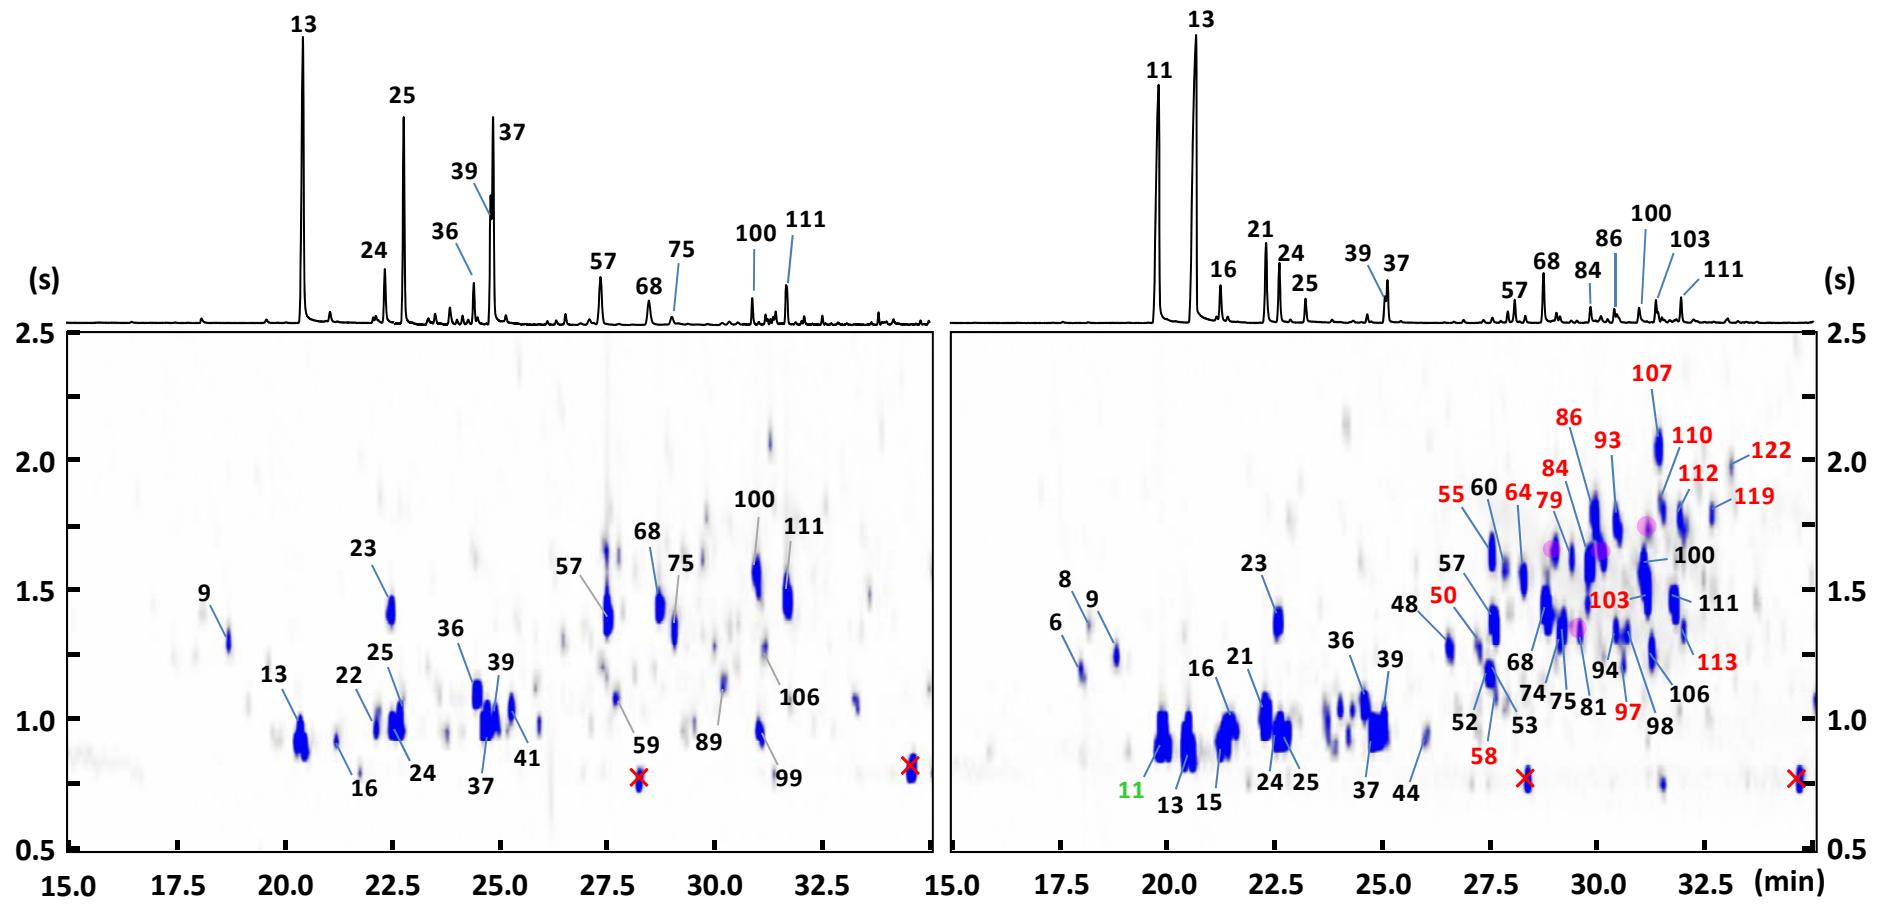

Fig. 7. Expansions of two-dimensional GC plots resulting from the GC × GC-MS analysis of cannabis herb (left) and hashish (right). These plots clearly enlightened the differences observed in the monoterpenic region (RI HP-5 ~800-1300) between the two sample types. Compounds are numbered according to tables 5 and 6. Those appearing with red numbers are assumed to be photo-oxidation products. (double column figure)

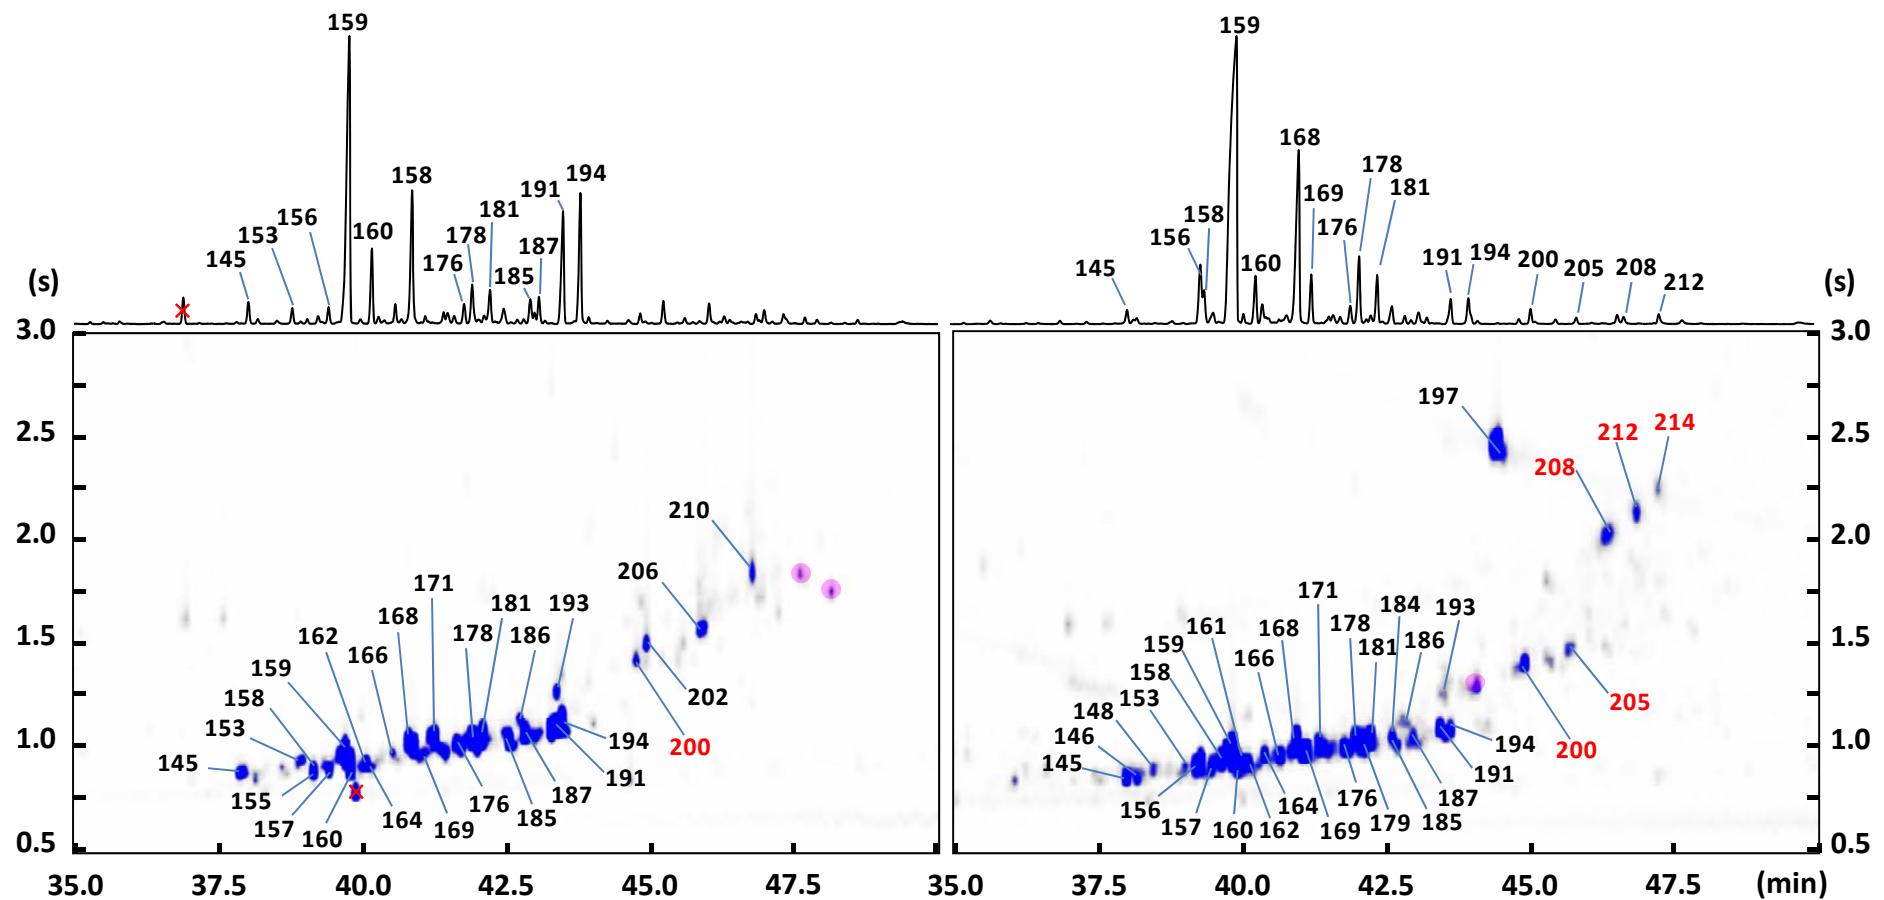

Fig. 8. Expansions of GC × GC plots of cannabis herb (left) and hashish (right) in the sesquiterpenic region (RI HP-5 ~1300-1700). Compounds are numbered according to tables 5 and 6. Those appearing with red numbers are assumed to be photo-oxidation products. (double column figure)

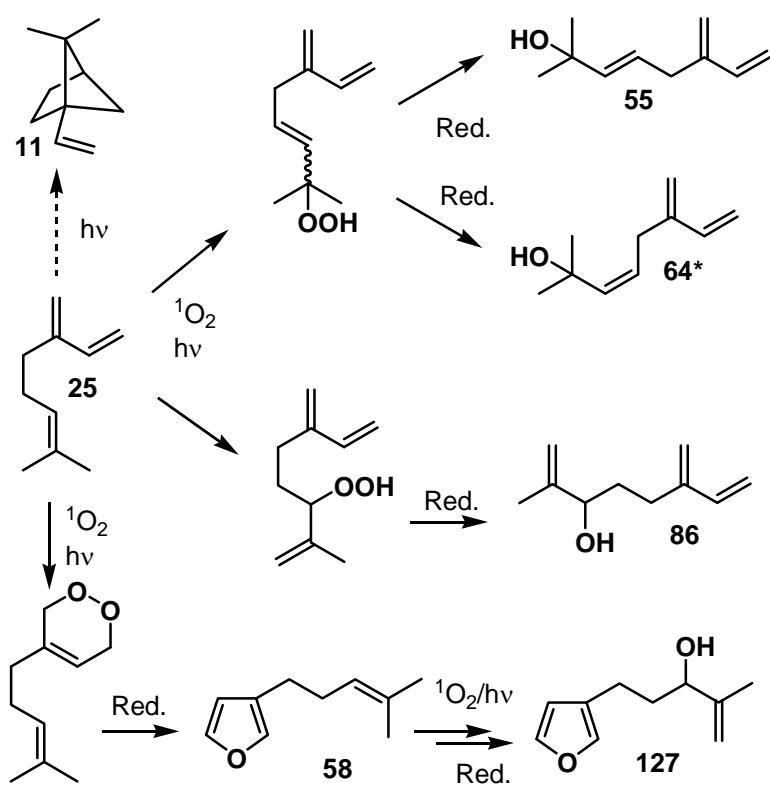

Fig. 9. Photo-oxidation reactions of β -myrcene **25** leading to the formation of compounds **55**, **58**, **64**, **86**, and **127**, all identified in hashish. (double column figure)

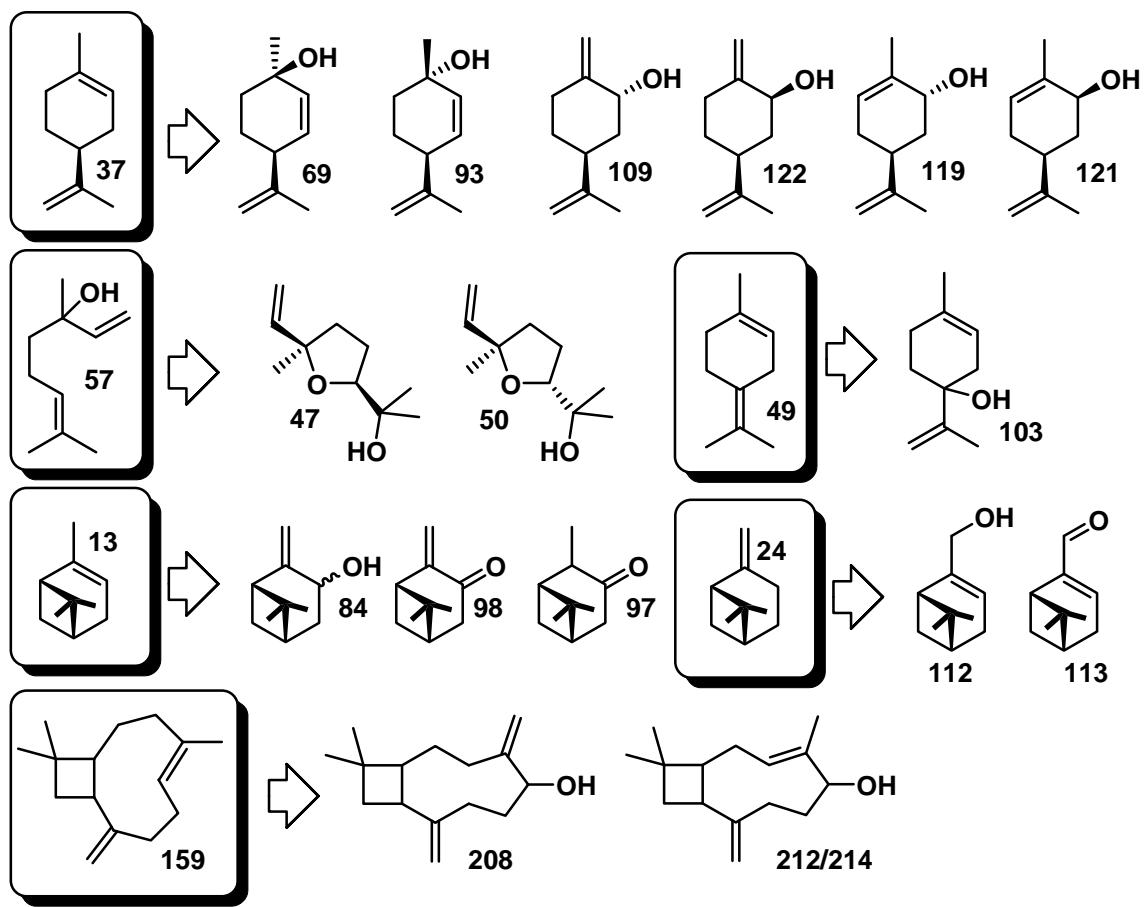

Fig. 10. Main photo-oxidation products observed in hashish samples. Their corresponding precursors are depicted within frames. (double column figure)

^a Compounds are numbered according to those cited in both tables 5 and 6. ^b Retention indices calculated against a series of C6-C24 n-alkanes; ^c Retention indices from the Terpenoids Library list (available at massfinder.com); ^d Retention indices from “Identification of Essential Oil Components By Gas Chromatography/Mass Spectrometry”, R.P Adams, 4th Ed. ^e Retention indices obtained from NIST webbook; ^f Retention indices obtained from *J Chrom A*, **2003**, 998, 201-211. ^g Exo-caryophyllene : 10,10-dimethyl-2,6-bis(methylene)bicyclo[7.2.0]undecane (CAS# 136296-38-3); ^h often coeluted with minor sesquiterpenes such as δ -cadinene ; ⁱ Samples of herb 2a-d indexed by INPS as coming from the same seizure; ^j samples 20-24 correspond to analyses performed at University of Nice (all other samples were analyzed at INPS); ^k Hashish sample #31 indexed by INPS as probably originating from Afghanistan; * unknown compound often coeluted with β -pinene; ** α -calacorene: often coeluted with Selina-4(15),7(11)-diene.

Table 2. Analysis of cannabis herb and hashish samples by HS-SPME-GC × GC-MS.

α -Terpinolene	1082	16, 20, 21, 22 , 23, 24 , 25 , 26, 27
<i>Monoterpenoids</i>		
Eucalyptol (1,8-cineole)	1024	17, 21, 22, 24, 25, 28, 29
<i>trans</i> -Sabinene hydrate	1053	16, 20
Fenchone	1069	17, 21
<i>cis</i> -Linalool oxide (furanoid)	1072	16, 20
Linalool	1086	16, 20, 21 , 23, 24, 25, 26
Fenchol	1099	17, 21, 23, 24, 26, 28
Ipsdienol	1123	18, 24
Borneol	1150	17, 21, 24, 25, 26
Terpinen-4-ol	1164	16, 20, 21, 22, 24, 25
α -Terpineol	1176	16, 20, 21, 22, 23, 24, 25, 26
<i>Sesquiterpenes</i>		
α -Cubebene	1355	17, 24
α -Ylangene	1376	18
α -Copaene	1379	17, 21
β -Elemene	1389	17 (γ), 21
Isocaryophyllene (syn. (Z)-caryophyllene)	1409	19 , 20, 22, 29
Longifolene	1417	17 , 20
<i>cis</i> - α -Bergamotene	1418	16 , 21, 22
(E)- β -Caryophyllene	1427	16 , 17 , 18, 19* , 20, 21 , 22 , 23 , 24 , 25 , 26 , 27 , 28, 29
<i>trans</i> - α -Bergamotene	1434	16 , 19* , 20, 21, 22 , 23 , 24, 25, 26, 27
α -Guaiene	1440	18, 23, 24, 25
(E)- β -Farnesene ^e	1446	16 , 19 , 20, 21, 23 , 24, 25, 26, 27
α -Humulene ^f	1455	16 , 17 , 18, 19 , 20, 21 , 22 , 23 , 24 , 25 , 26 , 27 , 28, 29
<i>allo</i> -Aromadendrene	1462	17, 21, 22, 24, 25
Curcumene, α - (RI for β : 1503)	1473	16 , 20, 26
γ -Muurolene	1474	24, 25
β -Selinene	1486	19 , 20, 21, 22, 24, 25, 29
α -Selinene	1494	16 , 18, 19 , 20, 21, 22, 24, 25, 26
Valencene	1494	22, 29
β -Bisabolene	1503	18, 22, 24, 25, 26
γ -Cadinene	1507	17, 21, 24, 25
δ -Cadinene	1520	17, 24, 25
Selina-4(15),7(17)-diene	1534	19 , 20
Selina-3,7(17)-diene	1542	19 , 20, 24, 25, 29
Germacrene-B	1552	22, 24, 25
<i>Sesquiterpenoids</i>		

Compound name	RI liter. ^a	Citations ^{b,c,d}
Nerolidol (RI for Z: 1522 ; E: 1553)		20, 24 (<i>E</i>), 25 (<i>E</i>)
Caryophyllene oxide	1578	16, 20, 21, 22, 23, 24, 25, 26
Humulene oxide	1593	20, 24
α -Guaiol	1593	20, 21, 23, 29
γ -Eudesmol	1618	20, 21, 23, 24, 25
β -Eudesmol	1641	21, 23, 25
α -Eudesmol	1653	21, 25
β -Bisabolol	1659	21, 25
α -Bisabolol	1673	20, 24, 25
epi- α -Bisabolol		21, 22

^a Retention indices from the literature mainly taken from the Terpenoids Library (Mass Finder 4.0) available online at http://massfinder.com/wiki/Terpenoids_Library_List

^b compounds listed here have been cited at least twice in the literature.

^c citations appearing in bold indicate the compound has been reported as present above 1%.

^d references 16-24 are dealing with essential oils (EO) of cannabis; references 25 and 26 are dealing with both EO and headspace analysis; references 27-29 are dealing with headspace constituents only.

^e probably wrongly reported as the (*Z*)- β -farnesene in references 21 and 23, no stereochemistry indicated in 16.

^f probably wrongly reported as β -humulene in references 16, 19, 20 and 25.

*an asterisk indicate that compounds were reported to coelute in the corresponding reference.

Table S2. Factors and their levels evaluated during the optimization of HS-SPME of hashish samples.

	Parameters	Level -	Level +
X1	Sample weight (g)	0.5	1.0
X2	SPME fiber	100 μ m PDMS	CAR/DVB/PDMS (Tri.)
X3	Temperature (°C)	22 (R.T.)	65
X4	Incubation time (min)	30	60
X5	Extraction time (min)	20	40

Table S3. Hadamard matrix for the experimental design.

Experim. #	X1	X2	X3	X4	X5
1	+	+	+	-	+
2	-	+	+	+	-
3	-	-	+	+	+
4	+	-	-	+	+
5	-	+	-	-	+
6	+	-	+	-	-
7	+	+	-	+	-
8	-	-	-	-	-

Table S4. Experimental datasheet summarizing the full experimental design.

Experim. #	Sample weight (g)	SPME fiber	Temp. (°C)	Incub. Time (min)	Extract. time (min)	Total area monoterpene	Total area sesquiterpenes	Area ratio mono./sesqui.
1	1.0	Tri.	65	30	40	2970050887	4030196821	0.74
2	0.5	Tri.	65	60	20	2340631996	3388024051	0.69
3	0.5	PDMS	65	60	40	3096816610	4123095709	0.75
4	1.0	PDMS	R.T.	60	40	2776641137	1580795373	1.76
5	0.5	Tri.	R.T.	30	40	1941254226	1618686461	1.20
6	1.0	PDMS	65	30	20	3255986890	3567518678	0.91
7	1.0	Tri.	R.T.	60	20	2921018612	1062763525	2.75
8	0.5	PDMS	R.T.	30	20	2292967457	946031499	2.42
